### 7: Desired State and Data

#### Slide 2

## **Objectives**

After completing this module, you should be able to

- > Understand when to use a template resource
- > Create a template file
- > Use ERB tags to display node data in a template
- > Define a template resource

©2015 Chef Software Inc.

7-2

In this module you will learn how to understand when to use a template resource, create a template file, use ERB tags to display node data in a template, define a template resource.

#### Slide 3

## **Cleaner Recipes**

In the last section we updated our two cookbooks to display information about our node.

We added this content to the file resource in their respective recipes.

©2015 Chef Software Inc.

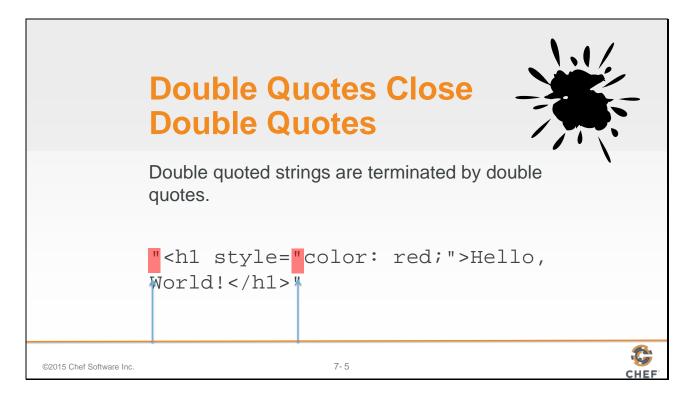

7-3

#### Slide 4

What if new changes are given to us for the website splash page? For each new addition we would need to return to this recipe and carefully paste the contents of the new HTML into the string value of the content attribute.

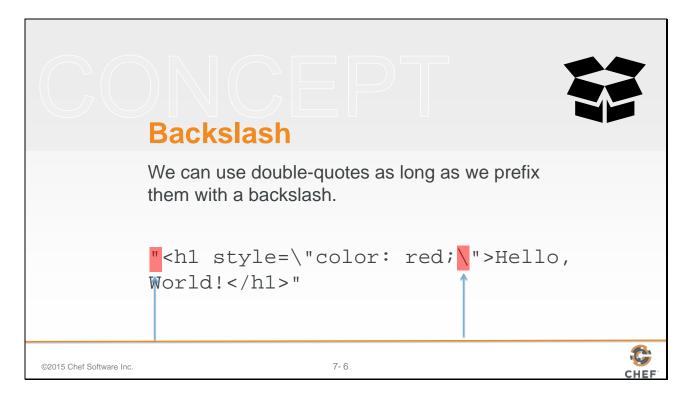

#### Slide 5

There are some things that you need to be careful of when working with double-quoted strings in Ruby:

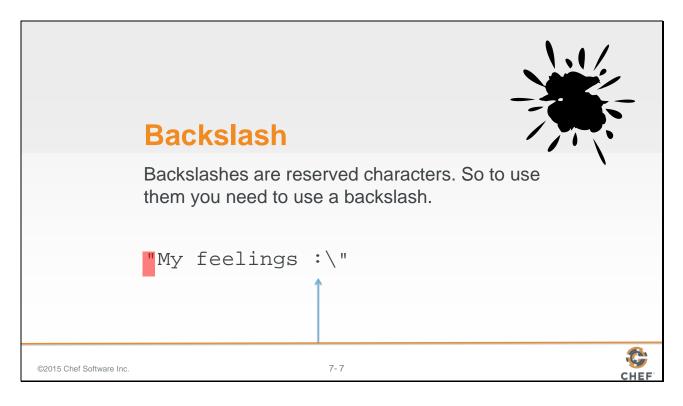

Double-quoted strings are terminated by double-quotes so if any of the text that we paste into this content field has double quotes it is going to have to be escaped.

#### Slide 6

With Ruby strings you can use the backslash character as an escape character. In this case, if you wanted to have a double-quote inside a double-quoted string, you would need to place a backslash before the double-quote.

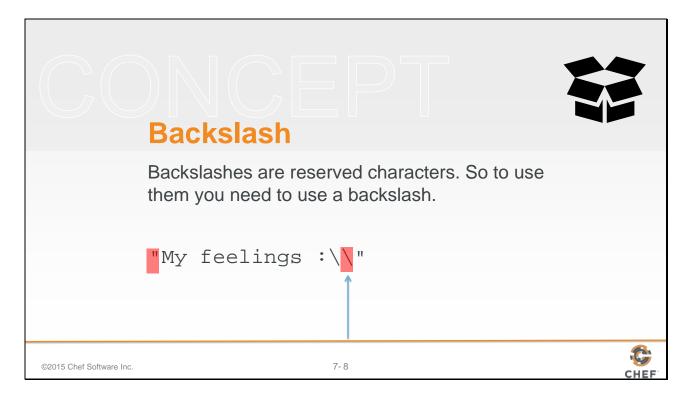

#### Slide 7

That also brings up an issue with continually-pasting text. You will also need to keep an eye out for backslash characters because backslash characters are now the escape character.

If you want to literally represent a backslash you'll need to use two-backslashes.

#### Slide 8

So every time text is pasted into the string value of the content attribute, you will need to find and replace all backslashes with double-backslashes and then replace all double-quotes with backslash double-quotes.

#### Slide 9

## **Unexpected Formatting**

```
file "/etc/motd" do
    content "This is the first line of the file.
        This is the second line. If I try and line it up...

Don't even think about pasting ASCII ART in here!

end

This is the first line of the file.

This is the second line. If I try and line it up...
```

Don't even think about pasting ASCII ART in here!

©2015 Chef Software Inc.

7-9

It is important to note that the file content may have some important formatting that might be easily overlooked when working with the content in a recipe file.

Besides that, if the size of the string value of the content field grows, it will consume the recipe--making it difficult to understand what is desired state and what is data.

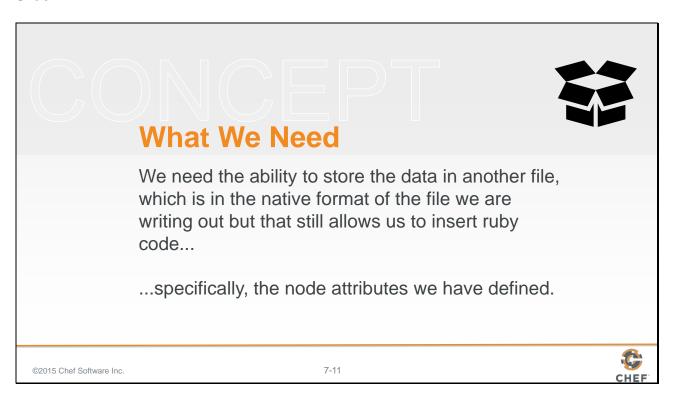

#### Slide 10

This could sound like a bug waiting to happen.

Any process that requires you to manually copy and paste values and then remember to escape out characters in a particular order, is likely going to lead to issues later when you deploy this recipe to production.

#### Slide 11

It is better to store this data in another file. The file would be native to whatever format is required so it you wouldn't need to escape any common characters.

But you still need a way to insert node attributes. So you really need a native file format that allows us to escape out to ruby.

#### Slide 12

To solve this problem, we need to read up on the file resource more or see if Chef provides alternatives.

#### Slide 13

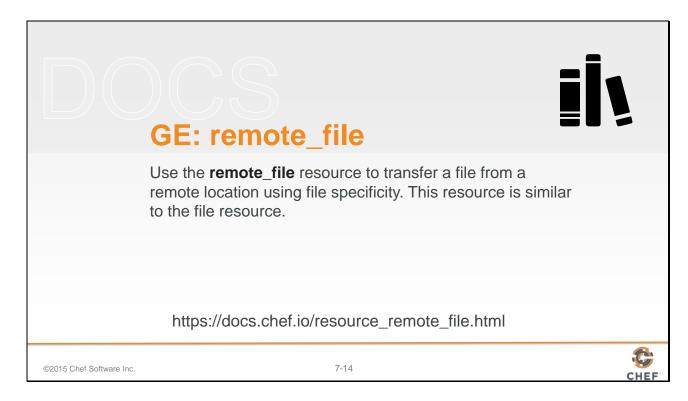

Let's start from what we know--the file resource. Open the documentation and see what it says and see if it gives us an clue to finding alternatives.

The file resource documentation suggests a couple of alternatives to using the file resource: cookbook\_file resource; template resource; and remote\_file resource.

Lets start with the remote\_file resource.

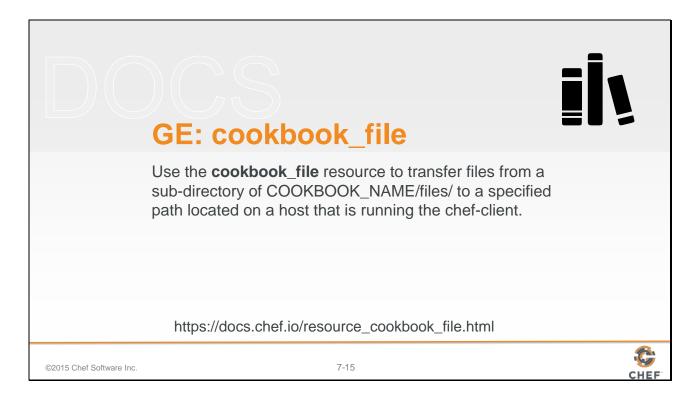

#### Slide 14

Reading the documentation for remote\_file, it seems that remote\_file is similar to file. Except remote\_file is used to specify a file at a remote location that is copied to a specified file path on the system.

So we could define our index file or message-of-the-day file on a remote system. But that does not allow us to insert attributes about the node we are currently on.

#### Slide 15

Reading the documentation for cookbook\_file, after the boiler-plate resource definition, it sounds as though a cookbook file is capable of...

#### Slide 16

```
cookbook_file's Source Match Up

$ tree cookbooks/apache/files/default
files/default
index.html

0 directories, 1 file
cookbook_file "/var/www/index.html" do
source "index.html"
end
```

...allowing us to store a file within our cookbook and then have that file transferred to a specified file path on the system.

While it sounds like it allows us to write a file in its native format, it does not sound as though the ability exists to escape out to access the node object and dynamically populate data.

#### Slide 17

Lets explore templates.

Reviewing the documentation, it seems as though it shares some similarities to the cookbook\_file resource.

#### Slide 18

```
Template File's Source Matches Up

$ tree cookbooks/apache/templates/default
templates/default
    index.html.erb

0 directories, 1 file
template "/var/www/index.html" do
source "index.html.erb"
end
```

A template can be placed in a particular directory within the cookbook and it will be delivered to a specified file path on the system.

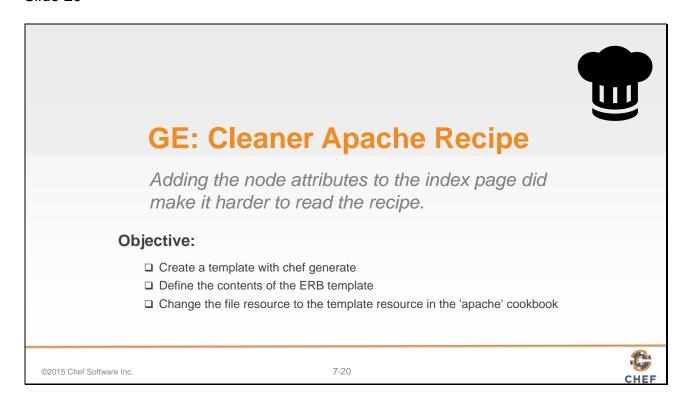

The biggest difference is that it says templates can contain ruby expressions and statements. This sounds like what we wanted: A native file format with the ability to insert information about our node.

#### Slide 19

And if we look at the bottom section about "Using Templates", we'll see more information about what is required and how we can use them to escape out to execute ruby code.

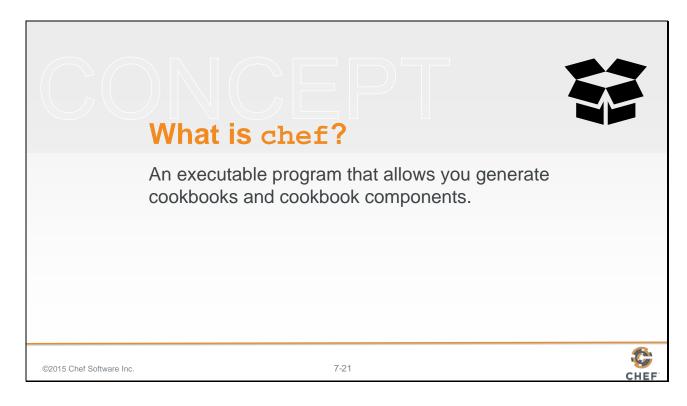

#### Slide 20

So our objective is clear. We need to use a template resource and create a template and then link them together.

Lets start by creating the actual template file and then we will update the recipe.

#### Slide 21

Remember that application Chef--the one that generated our cookbooks. Well it is able to generate cookbook components as well.

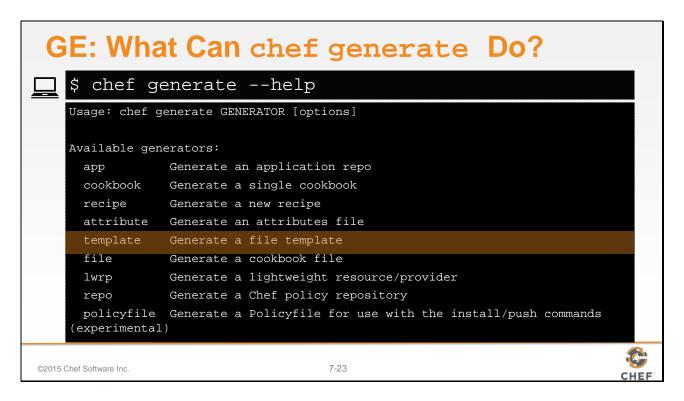

Templates and files (for cookbook\_files) are a few of the other things it can generate for us.

#### Slide 22

```
GE: What Can chef Do?
     chef --help
  Usage:
      chef -h/--help
      chef -v/--version
      chef command [arguments...] [options...]
  Available Commands:
                  Runs the command in context of the embedded ruby
      exec
                  Runs the `gem` command in context of the embedded ruby
      gem
                 Generate a new app, cookbook, or component
      shell-init Initialize your shell to use ChefDK as your primary ruby
      install
                  Install cookbooks from a Policyfile and generate a locked
   cookbook set
       ©2015 Chef Software Inc.
                                     7-22
```

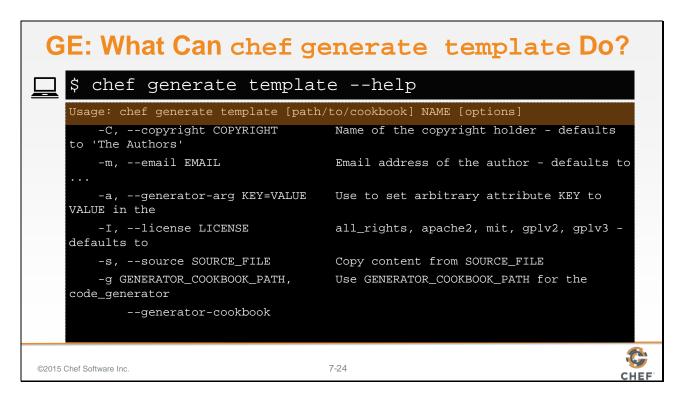

Lets use help to review the command again.

#### Slide 23

And lets ask for help about the 'generate' subcommand.

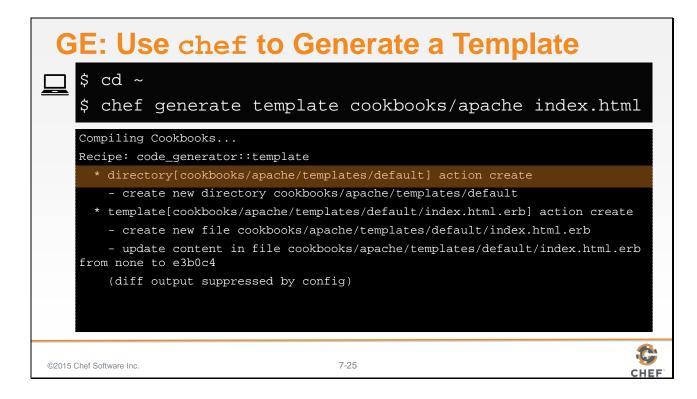

#### Slide 24

Finally lets ask for help for generating templates.

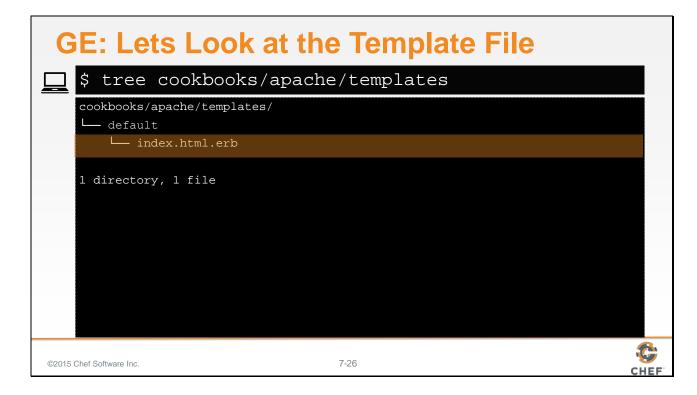

The command requires two parameters--the path to where the cookbook is located and the name of the template to generate. There are some other additional options but these two seem like the most important.

#### Slide 25

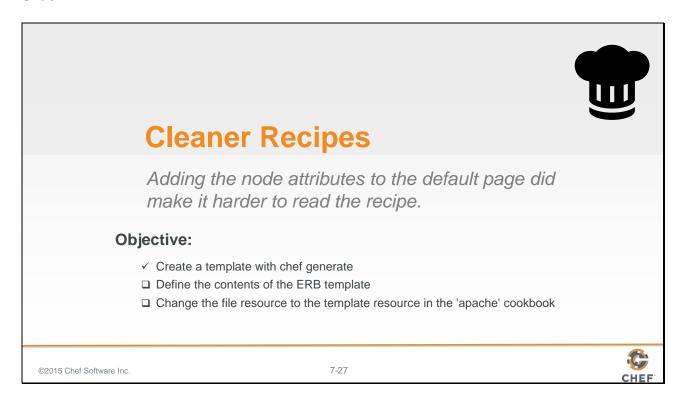

Use 'chef generate template' to create a template in the apache cookbook found in the cookbooks/apache directory and the file we want to create is named index.html.

#### Slide 26

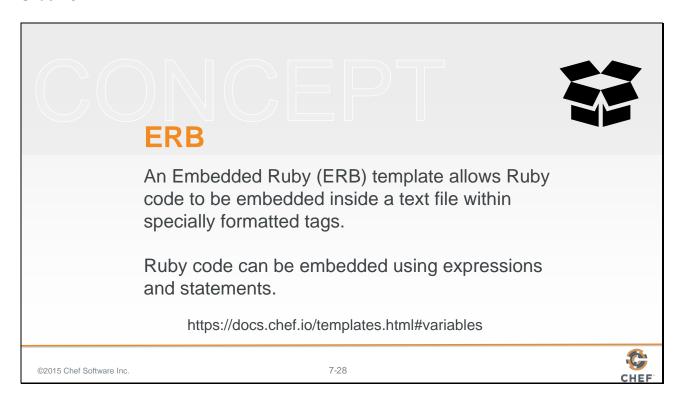

That is the first step. Now that the template exists, we are ready to define the content within the template file.

#### Slide 27

Now we need to understand what ERB means.

#### Slide 28

ERB template files are special files because they are the native file format we want to deploy but we are allowed to include special tags to execute ruby code to insert values or logically build the contents.

#### Slide 29

©2015 Chef Software Inc.

# 

7-29

Here is an example of a text file that has several ERB tags defined in it.

#### Slide 30

```
Text Within an ERB Template

(% if (50 + 50) == 100 %>
50 + 50 = <%= 50 + 50 %>
(% else %>
At some point all of MATH I learned in school changed.
(% end %>

Each ERB tag has a beginning tag and a matched ending tag.
```

Each ERB tag has a beginning tag and an ending tag.

#### Slide 31

The beginning tag is a less-than sign followed by a percent sign. The closing tag is a percent sign followed by a greater-than sign.

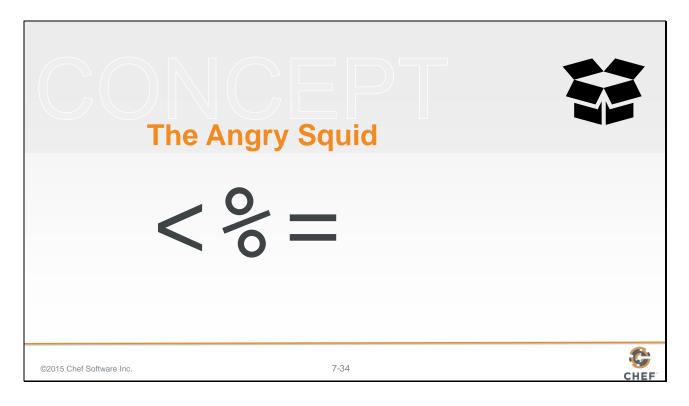

#### Slide 32

These tags are used to execute ruby but the results are not displayed.

#### Slide 33

ERB supports additional tags, one of those is one that allows you to output some variable or some ruby code. Here the example is going to display that 50 plus 50 equals the result of ruby calculating 50 plus 50 and then displaying the result.

#### Slide 34

The starting tag is different. It has an equals sign. This means show the value stored in a variable or the result of some calculation.

We often refer to this opening tag that outputs the content as the Angry Squid. The lessthan is its head, the percent sign as its eyes, and the equals sign its tentacles shooting away after blasting some ink.

#### Slide 35

```
GE: Move Our Source to the Template

-/cookbooks/apache/templates/default/index.html.erb

-/tml>
-/body>
-/h1>Hello, world!</h1>
-/h2>ipaddress: #{node["ipaddress"]}</h2>
-/h2>hostname: #{node["hostname"]}</h2>
-/body>
-/html>
```

With that in mind lets update the template with the current value of the file resource's content field.

Copying this literally into the file does not work because we no longer have the ability to use string interpolation within this html file. String interpolation only works within a ruby file between a double-quoted string.

#### Slide 36

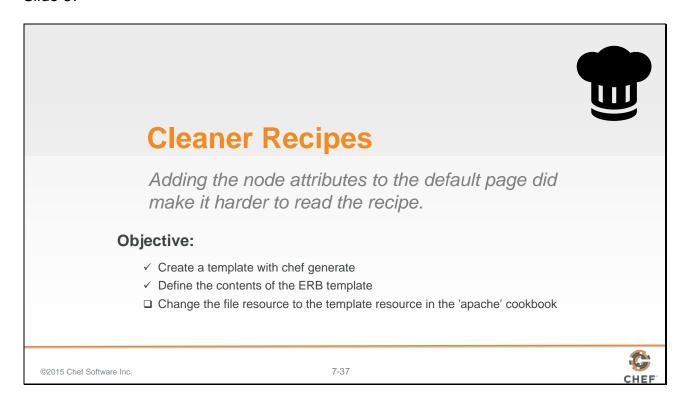

```
GE: Replace String Interpolation with ERB

-/cookbooks/apache/templates/default/index.html.erb

-/tml>
-/tml>
-/thml>
```

We are going to need to change string interpolation sequence with the ERB template syntax. And it seems for this content we want to display the output so we want to make sure that we are using ERB's angry squid opening tag.

# Slide 37

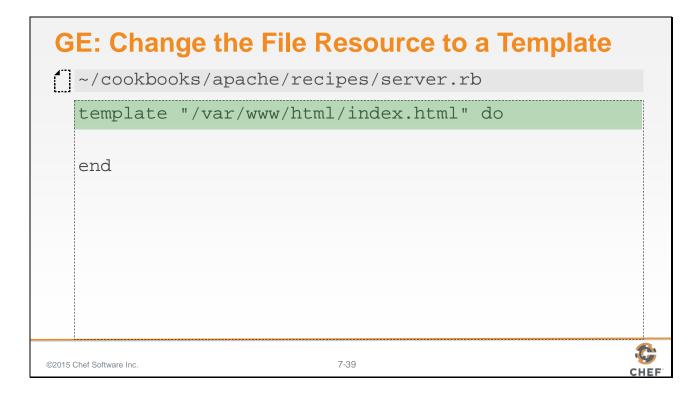

The template is created and the contents are correctly defined. It is time to update the recipe.

#### Slide 38

Lets open the apache cookbook's recipe named 'server'.

We will want to remove the content attribute from the file resource. Because that content is now in the template. But only if we use a template resource.

# Slide 39

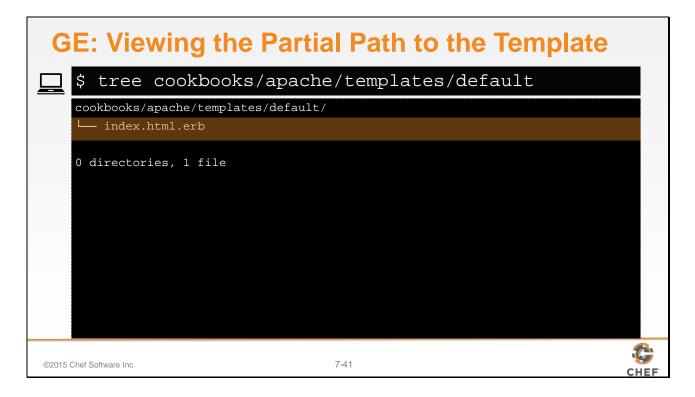

So its time to change the file resource to a template resource so that it can use the template file that we have defined.

#### Slide 40

Lastly we need to specify a source attribute which contains that path to the template we generated. This path is relative starting from within the cookbook's template directory.

#### Slide 41

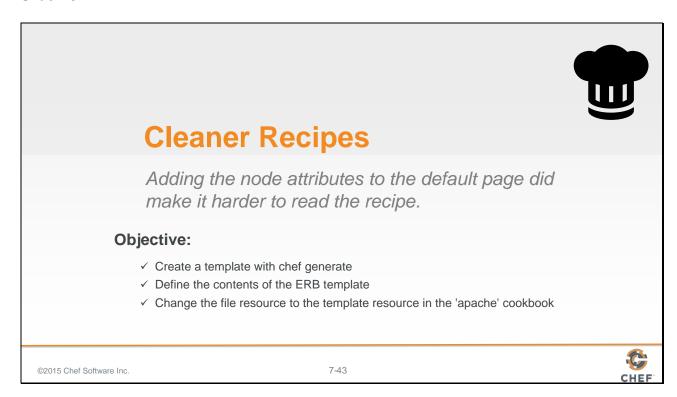

To visualize that with 'tree' we can run it with a path that places us right at the templates directory. So the results will be relative paths from the point specified.

And we see the filepath index.html.erb.

# Slide 42

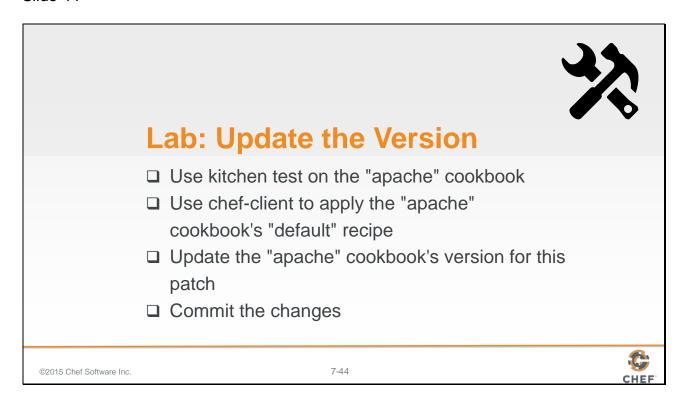

Now we have the path to our template so we can update the template resource's source attribute value.

#### Slide 43

We hopefully haven't changed the original goal of our recipe but we have made some changes.

#### Slide 44

In this lab, you will use 'kitchen' to verify the cookbook and use 'chef-client' to apply the cookbook. If everything is working then update the patch number and commit the changes to version control.

# Slide 45

```
Lab: Test the Cookbook

$ cd ~/cookbooks/apache
$ kitchen test

----> Starting Kitchen (v1.4.0)
----> Cleaning up any prior instances of <default-centos-67>
----> Destroying <default-centos-67>...
Finished destroying <default-centos-67> (0m0.00s).
----> Testing <default-centos-67>
----> Creating <default-centos-67>...
Sending build context to Docker daemon 2.56 kB
Sending build context to Docker daemon
Step 0: FROM centos:centos6
---> 72703a0520b7
```

Since kitchen is a cookbook testing tool, you need to move into the cookbook's directory.

Then run the 'kitchen test' command, addressing any issues if they show up.

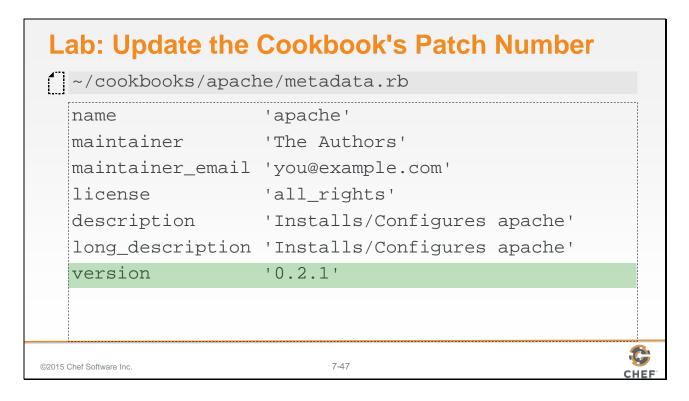

#### Slide 46

```
Lab: Change Directories and Apply the Cookbook
    $ cd ~
    $ sudo chef-client --local-mode -r "recipe[apache]"
    [2015-09-16T14:18:05+00:00] WARN: No config file found or specified on command line,
    using command line options.
    Starting Chef Client, version 12.3.0
    resolving cookbooks for run list: ["apache"]
    Synchronizing Cookbooks:
      - apache
    Compiling Cookbooks...
    [2015-09-16T14:18:09+00:00] WARN: Cloning resource attributes for service[httpd]
    from prior resource (CHEF-3694)
     [2015-09-16T14:18:09+00:00] WARN: Previous service[httpd]: /root/.chef/local-mode-
    cache/cache/cookbooks/apache/recipes/server.rb:8:in `from_file'
     [2015-09-16T14:18:09+00:00] WARN: Current service[httpd]: /root/.chef/local-mode-
     cache/ ...
©2015 Chef Software Inc
                                         7-46
```

When all the tests pass, return to the home directory, so you can execute 'chef-client'.

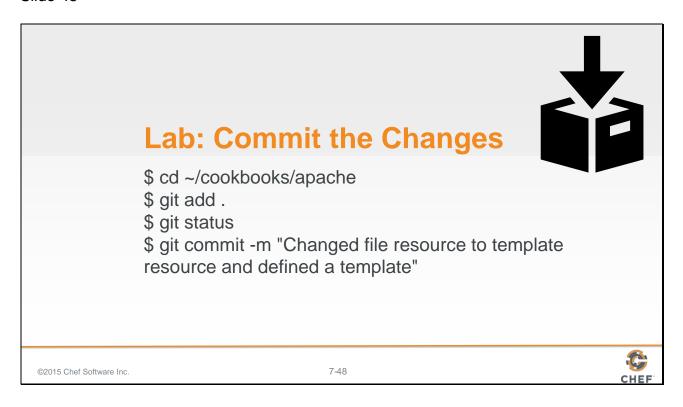

And then apply the apache cookbook's default recipe to the local system.

#### Slide 47

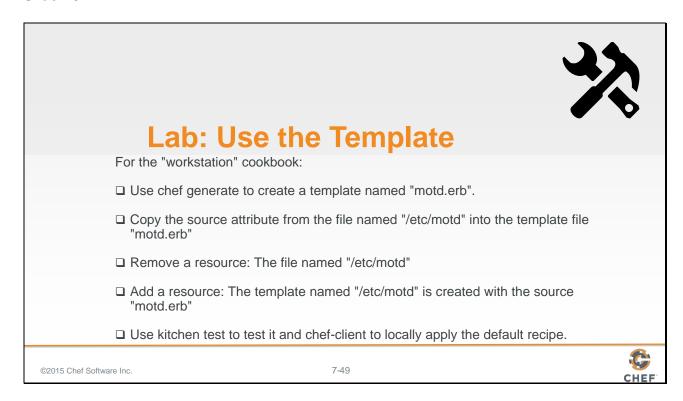

If everything converges correctly, update the version number. As mentioned previously, this is a patch fix.

#### Slide 48

Return to the cookbook directory and add all the changed files and commit them with a message.

#### Slide 49

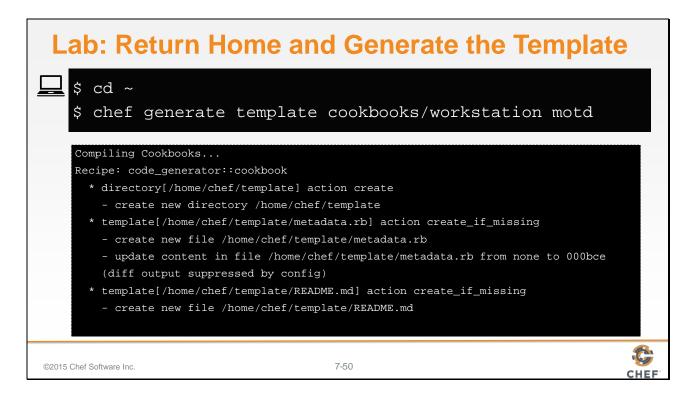

Its time to do that again--this time for the workstation cookbook.

Generate a template named 'motd', copy in the source attribute from the file resource, and then update it to use ERB tags.

Then come back to the recipe. Change it to a template resource and then add a source attribute whose value is that partial path to the new template you created.

#### Slide 50

Return to the home directory. Run the command to generate the template named 'motd' in the workstation cookbook.

#### Slide 51

We can start by copying and pasting the existing content for the Message of the Day file into the template file.

#### Slide 52

Replace all the string interpolation with ERB tags.

#### Slide 53

Remove the file resource from the setup recipe.

#### Slide 54

...and replace it with the Template resource. The source attribute specifies the file path 'motd.erb' - the new template file that was created.

#### Slide 55

```
Lab: Test the Cookbook

$ cd ~/cookbooks/workstation
$ kitchen test

----> Starting Kitchen (v1.4.0)
----> Cleaning up any prior instances of <default-centos-67>
----> Destroying <default-centos-67>...
Finished destroying <default-centos-67> (0m0.00s).
